

REMARKS

The specification has been amended to correct errors of a typographical and grammatical nature. Due to the number of corrections thereto, applicants submit herewith a Substitute Specification, along with a marked-up copy of the original specification for the Examiner's convenience. The substitute specification includes the changes as shown in the marked-up copy and includes no new matter. Therefore, entry of the Substitute Specification is respectfully requested.

The abstract has also been amended to more clearly describe the features of the present invention.

Also submitted herewith is a proposed amendment to the drawings, wherein Figs. 1 and 2 have been amended at this time. Upon receipt of the approval of the amendment to the drawings and receipt of a Notice of Allowance, the proposed drawing corrections will be effected in accordance with present practice.

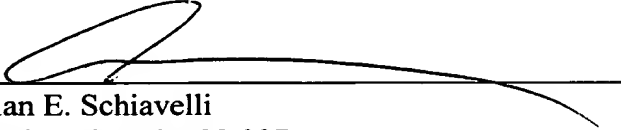

Entry of the preliminary amendments and examination of the application is respectfully requested.

To the extent necessary, applicant's petition for an extension of time under 37 CFR 1.136. Please charge any shortage in the fees due in connection with the filing of this paper, including extension of time fees, to Deposit Account No. 01-2135 (503.39781X00) and please credit any

excess fees to such deposit account.

Respectfully submitted,

ANTONELLI, TERRY, STOUT & KRAUS, LLP

REWRITTEN MARKED UP COPY

ABSTRACT

A gateway by which a network for performing communication periodically and a network for performing communication to an event ~~driven~~ can be effectively connected and a distributed system are provided. The gateway connecting different networks receives a ~~periodical~~ periodic message, and when a change of the received message is detected, it sends it the message as an event message, and delivers the message periodically.

GATEWAY AND DISTRIBUTED SYSTEM USING THE GATEWAY

TECHNICAL FIELD

This invention relates to a gateway for connecting a plurality of networks having different ^{characteristics} [characters], and a distributed system using this gateway.

BACKGROUND [TECHNIQUE] OF THE INVENTION

^{the development of the} In ^{on the automobile,} (a) recent automobile, various electronic ^{apparatuses} [apparatus] ^{have been} loaded, including (an) audio instruments, a navigation device, an engine controlling device, a driving device for a mission [etc.], for example, and these electronic apparatuses are connected to ^{different} networks depending upon their ^{characteristics} [characters]. To a network for an information system, ^{there is connected} an apparatus operating ^{in response to} [by] an input (input of an event) from the outside, such as ^{the output of} an audio instrument [], and ^{there is connected} to a network for a control system, an apparatus for outputting information at a predetermined period, such as an engine controlling apparatus [is connected].

Japanese Patent Application Laid-Open No.11-8647(1999) discloses a gateway for ^{use in} connecting [between] plural LANs which ^{have} (are) different [in] protocols.

However, in such prior art publication, there is no description ^{of} [for] a gateway connecting [the] networks which are different in character, ^{such as a} [one being] so-called information system network [], and ^a [the other] so-called control system network, for example. Specifically, there is ^{no disclosure} [not disclosed] in the above-mentioned publication ^{of} [the] transmission of information

between ^{an} [the] information system network in which information is transmitted in response to an event and ^a [the] control system network in which information is transmitted at a constant period.

SUMMARY

5 [DISCLOSURE] OF THE INVENTION

An object of this invention is to provide a gateway which can connect an information system network and a control system network and can ^{carry out the} [perform information] ^{of information} exchange between the information system network and the control system network, and
10 to provide a distributed system using this gateway.

Characteristic features of this invention for obtaining the above-mentioned object are as follows. The object of this invention can be achieved by ^{an} [the] individual or any combination of these characteristic features.

15 The gateway ^{operates to} [performs the] send and receive [of] a message which is transmitted periodically, ^{as well as to} [and the] send and receive [of] a message which is transmitted in response to an event, ^a or request or demand.

Also, the gateway, upon the detection of ^a [the] change [of] ^{an} ^{periodic} a [periodical] message received from one network, sends a message
20 to another network.

Also, the gateway periodically sends a message received from one network to another network.

DESCRIPTION

25 BRIEF [EXPLANATION] OF THE DRAWINGS

Fig. 1 is ^{block} a diagram showing the construction of a gateway according to one embodiment of this invention;

BEST MODE FOR EMBODYING THE INVENTION

Hereinafter, ^{various} embodiments of this invention will be ^{described} [explained] in detail ^{with reference to the} [using attached] drawings.

[First of all] A first embodiment of this invention will be explained. ^{with reference to Fig. 1} This ^{embodiment} [invention] is intended to handle an event ^{message} [message] mode, in which a message is output from a processing apparatus onto a network in response to the generation of an event, and a periodic ~~message~~ message mode, in which a message is output from the processing apparatus onto a network at a predetermined period, and [It enables the exchange of messages between a network to which the processing apparatus which outputs the event message is connected (hereinafter, "an information system network" is referred to) and a network to which the processing apparatus which outputs the periodic message, ^{is connected} (hereinafter, "a control system network" is referred to).

^{embodiment of the} Fig. 1 shows the construction of a gateway according to this invention. The gateway 10 is connected to the control system network 20 and the information system network 30. A CAN (Controller Area Network) is used for the control system network 20 and information system network 30 according to this embodiment.

The gateway 10 is comprised of a CPU 100, a memory 200, a bus 300, a control system network controller 400, a control system network driver 500, an information system network controller 600 and an information system network driver 700.

The CPU 100, the memory 200, the control system network

controller 400, ^{and} the information system network controller 600 are connected to the bus 300, which ^{operates as} (is) a signal line. The CPU 100 reads out ^a [the] program stored in the memory 200 [controlling] ^{and controls} the control system network controller 400, the control system network driver 500, the information system network controller 600 and the information system network driver 700, so that the exchange of [the] messages is performed between the information system network 20 and the control system network 30.

10 The control system network controller 400 is connected to the control system network driver 500, and the control system network driver 500 is connected to the control system network 20, so that [the] message transmission to the control system network 20 is carried out. The information system network controller 600 is connected to the information system network driver 700, 15 and the information system network driver 700 is connected to the information system network 30, so that [the] message transmission to the information system network 30 is carried out.

The memory 200 has a program stored ^{therein}, for running an OS (Operating System) and application programs stored ^{therein}, for a control system network communicating process 220, an information system network communicating process 230, a periodic ~~the~~ message sending process 240, a periodic ~~the~~ message receiving process 250, an event ^{message} (message) receiving process 260, an event message sending process 25 270 and a message value change detecting process 280; and, the memory 200 also has data storing areas, such as an event/period message buffer 201 and a period/event message buffer 202.

As the OS 210 in this embodiment, the OSEK-OS described in OSEK/VDX Operating System Version 2.0 revision 1 (1997) published by OSEK/VDX is utilized. Thus, by using ^{this} ~~the~~ OS, it is possible to cause the application programs to start up periodically as tasks, and ~~the~~ ^a message on the network to start up ^{in response to a} ~~by the~~ received event.

Also, as the control system network communicating process 220, the OSEK-COM described in OSEK/VDX Communication Version 2.1 revision 1 (1998) published by OSEK/VDX is utilized. The OSEK-COM ^{operates to perform} has its function effecting ^{message} both ~~of the message~~ sending ~~process~~ and ~~the~~ message receiving ~~process~~. Also, it has a function of specifying a message for reception ^{in accordance with an} ~~by~~ ID attached thereto. Therefore, it is possible to specify a message to be received ^{among} ~~within the~~ periodic messages on the control system network 20. ^a In case where a message is transmitted to the control system network 20, by calling out Send Message (), which is one API Service of the OSEK-COM from the application program for performing the periodic message sending process, it is possible to transmit the message onto the control system network 20 through the control system network controller 400. Also, in receiving ~~the~~ ^a message from the control system network 20, the predetermined ID of the message to be received ^{is} ~~has been~~ managed, and when ~~the~~ ^{messages} ~~messages~~ having the same ID are received, the control system network controller 400 performs ^a reception interrupt. In response to the reception interrupt from the control system network controller 400, an interrupt process for the message reception ^{processing} of the control system network communicating process

is started up, and it becomes possible to take the message on the control system network 20. The message fetched in can be read out by calling out Receive Message (), which is one of the API Services of the OSEK-COM.

5 In this embodiment, the information system network communicating process 230 also uses the OSEK-COM. Therefore, also in ^acase where ^a[the] message is sent to the information system network 30, an application program for performing the transmission process of the event message is executed by calling

10 out therefrom Send Message (), which is one of the API Services of the OSEK-COM, ^{whereby} the message can be sent onto the information system network 30 through the information system network controller 600. Also, in receiving ^a[the] message from the information system network 30, the predetermined ID of the

15 message to be received ^{is} [has been] managed, and when ^{messages} [the messages] having the same ID are received, the information system network controller 600 performs ^areception interrupt. In response to the reception interrupt from the information system network controller 600, an interrupt process for the message reception

20 of the information system network communicating process is started up, and it becomes possible to take the message on the information system network 30. The message fetched in can be read out by calling out Receive Message (), which is one of the API Services of the OSEK-COM.

25 Next, the operation of the gateway 10 according to this embodiment will be explained. First, the case where a message is transferred from the control system network 20, ^{which handles} [handling the]

periodic ^{messages,} [message] to the information system network 30 ^{, which handles} [handling],
 [the] event messages, will be explained.

As stated above, when the control system network controller 400 receives a message having a predetermined ID from among a plurality of periodic ~~the~~ messages on the control system network, it ^{will} perform an interruption. In response thereto, the OS 210 starts up the program of the periodic ~~the~~ message receiving process 250. This program of the periodic ~~the~~ message receiving process 250 is executed as one task. Since ^{will transmit messages} [on] the control system network 20 ^{the message is transmitted} periodically, this process (task) is also started up periodically.

The processing flow of a periodic ~~the~~ message receiving Process 2500, which is ^{part} [the process] of the periodic ~~the~~ message receiving process 250, will be explained ^{with reference to} [using] Fig. 2. First, the periodic ~~the~~ message receiving Process 2500 reads out a received message which was taken from the control system network 20 (Process 2501). This is executed by calling out Receive Message () of the control system network communicating process 220, as mentioned above.

Next, the message read out is stored in the period/event message buffer 202 (Process 2502). Now, the construction of the period/event message buffer 202 will be explained ^{with reference to} [using] Fig. 3. As explained above, a message has ^{an} ID (identifier) attached thereto. The period/event message buffer 202 includes a message ID storing area 20210, a this-time-value (value of the most recent message) storing area 20220 and a last-time-value (value of the message received most previously after the most recent message)

storing area 20230. Further, these areas are divided into storing areas per ID. That is, the ID storing area 20210 comprises an area 20211, an area 20212, an area 20213, etc. The this-time-value storing area 20220 comprises an area 20221, an
 5 area 20222, an area 20223, etc. per respective ID. The last-time-value storing area 20230 also comprises an area 20231, an area 20232, an area 20233, etc. per ID. For example, the message of ID 2 is stored so that the value (2) of its ID is memorized in the area 20211, the this-time-value (20) is memorized in the
 10 area 20221 and the last-time-value (18) is memorized in the area 20231.

In Process 2502, the value of the message read out is stored in the storing area of the this-time-value corresponding to the ID of this message. For example, in the case of the message
 15 of which ^{the} ID is 2, the value of the message read out is stored in the area 20221. In the case of the message having ^{an} ID of 6, the value of the message read out is stored in the area 20222.

Lastly, a message value change detecting process 2800 is started up (Process 2503). In starting up it, the message ID
 20 of the received message is given.

Next, the message value change detecting process 2800, which is ^{part} (the process) of the message value change detecting process 280, will be explained ^{with reference to} using Fig. 4. The message value change detecting process 280 is started up from the periodic message
 25 receiving process, as explained above.

The message value change detecting process 2800, when started up, first reads out the message stored in the period/event

message buffer 202 to check whether or not the this-time-value of the received message is ^{different} [different] from the last-time-value thereof (Process 2801). For example, if in Fig. 3 the ID of the message is 2, both are different since its this-time value
 5 is 20 and its last-time-value is 18. If the ID of the message is 6, both are the same since its this-time-value is 6400 and its last-time-value is also 6400.

If the last-time-value and the this-time-value are different from each other, the event message sending process
 10 270 is started up (Process 2802), whereas if the last-time-value and the this-time-value are the same, the processing is completed without any additional process.

Next, an event message sending process 2700, which is ^{the part} (the) ^{program} of the event message sending process 270, will be explained
 15 ^{with reference to} (by using) Fig. 5. The event message sending process 2700 is started up in ^a case where the value of the message fetched from the control system network is different from the last-time-value.

First, the event message sending process 2700 reads out the this-time-value of the message sent from the period/event
 20 message buffer 202 (Process 2701). For example, in Fig. 3, if the message having ^{an} (its) ID of 2 is intended to be sent, the ^{time} this-[time]-value 20 stored in the area 20221 is read out.

Next, by calling up the information system network communication process 230, the transmission of the message is
 25 effected (Process 2702). This can be executed by calling out Send Message (), as stated above. In this embodiment, the messages are transmitted by using the same ID both in the control

system network and in the information system network. Although different IDs can be used in both of the control system and the information system, in ^{such} this case it is ^{necessary} needed to memorize the correspondence between the ID used in the control system and the ID used in the information system.

5 Lastly, the this-time-value of the periodic event message buffer 202 is stored as the last-time-value (Process 2703). For example, in Fig. 3, in the case of the message having ^{an} the ID of 2, the value which was stored in the area 20221 is stored in the area 20231.

The above-described explanation ^{is directed to} (is) the operation for transferring ^a the message from the control system network 20, ^{which handles} handling the periodic messages, to the information system network 30, ^{which handles} handling the event messages.

15 An example of ^{the} operation for message transfer from the control system network 20 to the information system network 30 will be explained ^{with reference to} using Fig. 6. Fig. 6 shows ^P that, for the message having the ID of 2 in Fig. 3, the reception timing of the periodic message from the control system network 20, the transmission timing of the event message to the information system network 30, and the change of the storing area 20221 for the this-time-value of the message having the ID of 2 of the period/event message buffer. ^{In the} The figure ^{is represented} shows the flow of time downwardly.

25 The periodic ^{are generated} messages ^{as messages} (is) at a constant period and are received in the way of 20251, 20252, 20253, 20254, 20255. Incidentally, in this case, it is supposed that before the

periodic message 20251 is received, the this-time-value of the message is 15. The value of the periodic~~ly~~ message 20251 is 15, the values of^{messages} 20252, 20253 and 20254 are 18 and the value of^{message} 20255 is 20. When the periodic~~ly~~ message 20252 is received,

5 the this-time-value changes from 15 to 18, and, at this timing^{time}, the event message 20261 having ^aits value of 18 is transferred.

Also, when the periodic~~ly~~ message 20255 is received, the this-time-value changes from 18 to 20, and, at this ^{time}timing, the event message 20262 having ^aits value of 20 is transmitted.

10 As explained above, ^{only that}the message for the control system network 20, which is received periodically, ^{and which,} only at the time when, ^{has a which} its value is different from the value which was received at the last time, is transferred to the information system network 30.

Next, message transfer from the information system network 30, ^{which handles} handling the event messages, to the control system network 20, ^{which handles} handling the periodic~~ly~~ messages, will be explained. In this embodiment, it is ^{presumed} supposed that all of the messages of the control system network 20 ^{have} are the same (in) sending period.

20 The event message receiving process 260 is executed as one task. This task is started up in response to the reception (event) of ^athe message on the information system network by means of the OS 210. Since on the information system network 30 the message is delivered in response to an event, this process (task) is also started up periodically in response to this event.

25 The flow of an event message receiving process 2600, which is ^{part} (the process) of the event message receiving process 260, will be explained ^{with reference to} (using) Fig. 7. The event message receiving process

2600 first reads out the received message fetched from the information system network 30 (Process 2601). This is executed by calling out Receive Message () of the information system network communicating process 230, as explained above.

5 Next, the message read out is stored in the event/period message buffer 201 (Process 2602). Now, the construction of the event/period message buffer 201 will be explained ^{with reference to} using Fig.

8. The event/period message buffer 201 has a message ID storing area 20110 and a value storing area 20120. Further, these areas
10 are divided into storing areas per ID. That is, the ID storing area 20110 is comprised of an area 20111, an area 20112, an area 20113, etc. The value storing area 20120 is comprised of an area 20121, an area 20122, an area 20123, etc. In Fig. 8, for example, in the case of the message having the ID value of 1,
15 the value of the message read out is stored in the area 20121. In the case of the message having the ID value of 5, the value of the message read out is stored in the area 20122.

Next, a periodic~~240~~ message sending process ²⁴⁰⁰ (240) which is ^{part} of the periodic~~240~~ message sending process 240, will
20 be explained ^{with reference to} (by using) Fig. 9. The periodic~~240~~ message sending process ²⁴⁰⁰ (240) is started up periodically by the OS 210 in accordance with the transmission period of the message of the control system network. As mentioned above, in one embodiment of this invention, it is ^{presumed} [supposed] that the transmission period of all of the messages
25 of the control system network 20 is the same.

The periodic~~240~~ message sending process 2400 first reads out the value of the message to be delivered from the event/period

message buffer 201 (Process 2401). Incidentally, all of the messages to be sent are ^{managed} ~~administrated~~ ^{reference to} with their IDs. For example, in Fig. 8, in ^a case where the message having ^{an} (its) ID of 1 has been registered as the message to be sent, the this-time-value 100
 5 stored in the area 20121 is read out.

Thereafter, the control system network communicating process 220 is called out to ^{effect} ~~perform~~ the transmission of the message (Process 2402). This can be achieved by calling out Send Message (), as mentioned above. In this embodiment, the
 10 messages are transferred with the same ID in both ~~of~~ the control system and the information system, as mentioned above. Although different IDs can be used in the control system and the information system, in ^{such} ~~this~~ case, it is ^{necessary} ~~needed~~ to memorize the correspondence between the ID used in the control system and the ID used in
 15 the information system.

The above-mentioned process 2401 and process 2402 are repeated until the ^{processing of} ~~processes for~~ all messages ^{is} ~~are~~ completed (Process 2403).

The above, ^{description} ~~is~~ ^{limited to the operation of} the message transferring ^{messages} ~~operation~~ from the information system network 30 ^{which handles} ~~handling the~~ event messages, to the control system network 20 ^{which handles} ~~handling the~~ periodic messages.

An example of the ^{operation of} ~~transferring~~ ^{messages} ~~operation~~ from the information system network 30 to the control system network 20 will be explained ^{with reference to} ~~using~~ Fig. 10. ~~P~~ Fig. 10 shows, for the message
 25 having the ID of 1 in Fig. 7, the reception timing of the event message ^{received} from the information system network, the transmission timing of the periodic ~~message~~ message to the control system network

the value in
 20, and the change of *the* storing area 20121 *(in the value)* of the message having the ID of 1 in the event/period message buffer. In the figure, the downward flow of time indicates the passage of time.

5 The event messages are received *as messages* *(in the way of)* 20161, 20162 and 20163. The value of the event message 20161 is 80, the value *message* of 20162 is 90, and the value of 20163 is 100. On the other hand, the periodic *message generated* messages are *as messages* at a constant period, and are delivered *(in the way of)* 20151, 20152, 20153, 20154 and 20155.

10 As the value of the periodic *message* message, the value in the storing area 20151 for the message value at the point of time of the delivery is used. Therefore, the values of the periodic *message* messages 20151, 20152 and 20153 are 80, and the values of the periodic messages 20154 and 20155 are 100.

15 Incidentally, *has been* *although* *in response to* *although* after the periodic *message* message 20153 *was* delivered, the value changes to 90 *(by)* the reception of the event message 20162, this event message having the value of 90 is not delivered, since before the next periodic message is delivered, the value changes to 100 *in response to* *(by)* the reception of the event message 20163.

As mentioned above, the messages of the information system network as received periodically in response to events are delivered to the control system network periodically.

25 An example of a distributed system for an automobile using the gateway of this embodiment is shown in Fig. 11. This distributed system *is comprised of* *(has)* two networks, a control system network 20 and an information system network 30, which are connected

through the gateway 10, as explained above.

To the control system network 20, ^{there is connected} the gateway 10, as well as an engine controlling unit 40 for controlling ^{the automobile} an engine and an ACC (Adaptive Cruise Control) controlling unit 50 for performing automobile travelling control to maintain the distance between ^{it and} a preceding car constant. ^{are connected}. Between the engine controlling unit, the ACC controlling unit and the gateway, ^{way of} the information is exchanged by ^{the} periodic messages.

To the information system network 30, ^{there is connected} the gateway 10, as well as a navigation system 60 for performing course guidance and an internet terminal 70 for connecting to the internet to gather information ^{are connected}. Between the navigation system, the internet terminal and the gateway, ^{the} information is exchanged by ^{way of} the event ^{messages} messages.

With such ^a system construction, it is possible to exchange ^{the} information between the navigation system and the ACC unit or between the navigation system and the engine controlling unit. For example, it is possible to realize the function of performing inter-car distance control within ^a the range below the restricted speed by delivering course limited speed information from the navigation system to the ACC unit. Also, by delivering engine status information, such as engine speed or the like, from the engine controlling unit to the navigation system, it is possible to observe the engine status on the screen of the navigation system.

^{foregoing} The above was the detailed explanation ^{was directed} as to one embodiment

of this invention.

In accordance with ^{an} [one embodiment of] this invention, in [the] ^a distributed system having [the] ^{an} information system network and control system network within an automobile, [there exists] 5 [the effect that] a periodic ^{message} message suitable ^{for the} [to] exchange [the] information for control can be used in the control system network and an event ^{message} [message] suitable ^{for} [to] exchange [the] information for information processing can be used in the information system network, and [that] the control system network and the information 10 system network in the automobile can be connected effectively.

Also, in accordance with [one embodiment of] this invention, the periodic message receiving process ^{is} [was] started up in response to [the] ^a received event of [the] ^a message on the control system network. With it, it is possible to start up the receiving process as 15 soon as the periodic ^{message is received} [message reaches], and also to deliver the event message immediately ^{in response to a} [upon the] change of value. ^{As a result} [by this], [the effect is provided that] any time delay following the message transfer from the control system network to the information system network can be minimized.

Also, ^{the above-described} in accordance with ^{invention} [one embodiment of this application], both [of] the control system network and the information system network ^{were configured} [was arranged by] using ^a [the] DAM network. Thus, by using the same kind of network in both networks, [the effect that] it is possible to make the system construction simple [is provided], 20 Also, [there exists the effect that] in the hardware, it is possible to use a micro-controller which houses the CPU, the memory and two CAN controllers, [and] whereby the gateway can be installed 25

compactly.

The control network 20 according to ^{the above-described} ~~one~~ ^a ~~embodiment~~ ^{network} of this invention was constructed using ~~(the)~~ CAN, but a network such as SAE/J1850, TTP (Time-Triggered Protocol) or the like may be used.

5 Also, in ^{accordance with} ~~one~~ ^{network} embodiment of this invention, the CAN was used in the information system network, but instead, a network such as D2B Optical, IDB (ITS DATA Bus), VAN (Vehicle Area Network) or the like may be used. It is possible to use different networks between the control system network and the information system
10 network. Since these various networks can be used, ~~(the effect)~~ ^(is provided that) it is possible to cope with a wider range of automobile systems. Also, ~~(there exists the effect that)~~ by using a high speed network, it is possible to realize a system with high performance.

15 In ^{the above-described} ~~one~~ ^a ~~embodiment~~ ^{network} of this invention, ~~(the)~~ ⁹ network communication process according to the OSEK-COM specification was used in the control system network communicating process 220 and the information system network communicating process 230. However, it is possible to use a control system network
20 communicating process or information system network communicating process according to a specification, such as IDB or the like. With this, ~~(the effect is provided that)~~ it is possible to apply ^{the invention} ~~(it)~~ to a wider range of automobile systems.

In ^{the above-described} ~~one~~ ^{network} embodiment of this invention, the transmission
25 period of the control network was made constant regardless of the message, but it is possible to change the period per message. In this case, it is ^{necessary} ~~(needed)~~ to memorize in the memory 200 the

correspondence between the ID and the transmission timing of the periodic¹ message. The OS 210 starts up the control system network communicating process 220 in conformity to the transmission timing of the periodic² message, and transfers

5 the ID of the message to be sent. The control system network communicating process 220, on the basis of the ID transferred from the OS 210, reads out the message^{having the} of which ID ^{is} agrees from the event/period message buffer, and performs the message transmitting process. Thus, (the effect is provided that) it is

10 possible to set up the most appropriate transmission period per message and to use the network effectively.

In ^{the above-described} [said one] embodiment of this invention, ^{effected} (the) bi-directional message transfer was ^{made} between the control system network and the information system network. However,

15 it may be modified to one directional transfer from the control system network to the information system network or from the information system network to the control system network. Thus, (the effect is given that) the exchange of information is limited so as ^{the} (thereby) to improve security.

20 In ^{the above-described} [said one] embodiment of this invention, the periodic³ message receiving process was started up in response to the reception ^a (event) of (the) message on the control system network. However, it may be started up at the same period as the periodic⁴ message.

25 Now, ^a (the) case where the periodic⁵ message receiving process is started up at the same period⁶ as the periodic⁶ message will be explained. In this case, the correspondence between

the message ID to be received and the startup timing of the periodic message receiving process and the correspondence between the message ID to be sent and the startup timing of the periodic message sending process are stored in the memory 200.

5 The OS 210 manages the startup timing of the periodic message receiving process and the startup timing of the periodic message sending process, and starts the periodic message receiving process 250 and the periodic message sending process 240. Also, the OS 210, when starting up the periodic message
 10 sending process 240, delivers the periodic message ID to be sent. In response thereto, the periodic message sending process shown in Fig. 9 is carried out, and the message corresponding to the delivered ID is transmitted. Also, the OS 210, when starting up the periodic message receiving process
 15 250, delivers the periodic message ID to be received. In response thereto, the periodic message receiving process shown in Fig. 2 is executed, and the reception of the message corresponding to the delivered ID is performed.

Also, the periodic message receiving process may be
 20 performed as the same task as the periodic message sending process. By this, [the effect is provided that] it is possible to make the task construction simple.

In ^{the above-described} (said one) embodiment of this invention, the OS was used and the task was started up ^{under control} by the function of the OS. However,
 — 25 instead, it is possible to start up and execute, without the OS, the periodic message receiving process by interrupt from the control system network controller, the event message receiving

process by interrupt from the information system network controller and the periodic~~all~~ message sending process by interrupt from a timer. Thus, ^athe effect is provided that ^{the}the OS becomes unnecessary and ^{the above-described}the reduction of cost can be achieved.

5 In ^{the above-described}said one embodiment of this invention, one control system network and one information system network were connected. ^{thus}So, the networks 20 and 30, the network controllers 400 and 600, and the network drivers 50 and 700 corresponding to the control system network and information system network, respectively, 10 were provided. However, instead, it is possible to connect a plurality of control system networks and a plurality of information system networks. To this end, it is ^{necessary}needed to provide ^{a number of}the control system network controllers, ^{a number of}the control system network drivers and ^{a number of}the control system networks corresponding 15 to the number of the plurality of control system networks, respectively. Further, in the control system network communicating process 220, a function for performing allocation to this plurality of control system networks on the basis of the network IDs is provided. Also, ^{respective number of}the information system 20 network controllers, the information system network drivers and the information system networks, the respective numbers correspond~~ing~~ to the number of the plurality of information system networks [are provided], and a function is provided for performing allocation to these plurality of information system 25 networks. ^{in way}By this, ^{is possible to}the effect is provided that it can cope with a large-scale system.

In ^{the}said control system according to ^{the above-described}one embodiment of this

invention, only the periodic^{the} message was used. However, instead, it is possible to use ^{a mixture of} ~~mixed~~ event ^{messages} ~~message~~ and periodic^{the} messages in the control system network. In this case, at the time of ^{the} transfer from the control system network to the information system network, the periodic^{the} message is transferred after it ^{is} ~~was~~ converted to ^{an} ~~the~~ event message, as in the ^{described} ~~one~~ embodiment of the invention, whereas the event message is ^{transferred} ~~transfer~~ as it is. Also, in the case of ~~the~~ transfer from the information system network to the control system network,

10 there are ~~the~~ methods for transforming ^{an} ~~the~~ event message into ^{described} ~~the~~ periodic^{the} message, as in the ~~one~~ embodiment of this invention, and for transferring it as it is. It is possible to properly use them depending upon the message. ^{In way} ~~By this~~, ^{the effect is} ~~the effect is~~ ^{an} ~~provided that~~ it is possible to use ^{message} ~~the~~ event ~~message~~ also in

15 the control system^{the}; and, ^a ~~in~~ case where information having lesser changes is exchanged, it is possible to reduce the load of the network.

the above-described

In the information system network according to ~~said one~~,^{the above-described} embodiment of this invention, only the event message was used.

20 However, instead, it is possible to use ^{a mixture of} ~~mixed~~ event ^{messages} ~~message~~ and periodic^{the} messages in the information system network. In this case, when the transfer from the information system network to the control system network is carried out, the event message is transferred after ^{it} ~~is~~ ^{above-described} ~~was~~ transformed into ^a ~~the~~ periodic^{the} message, as in the case of the ~~one~~ embodiment of this invention,

25 whereas the periodic^{the} message is ^{transferred} ~~trans~~ as it is. In the case of ~~the~~ transfer from ^{the} control system network to the information

system network, there are ^{an} ~~the~~ methods for transforming ^{above - described} ~~the~~ periodic message into ^{an} ~~the~~ event message, as in the ^{above - described} ~~one~~ embodiment of this invention, and for transferring it as ~~the~~ periodic message ^{is}. It is possible to properly use them depending upon the message. ^{In way} ~~By~~ this, ~~the~~ effect is provided that it is possible to use the periodic message also in the information system, and to improve real-time capacity as to multi-media information, such as an image, and ^{an} audio.

In the ^{above - described} distributed system according to ~~said one embodiment~~ of this invention, the control system network and the information system network were connected through ^a ~~the~~ gateway which is ^a ~~of~~ ^{the} type of ^{an} independent arrangement, but the gateway function may be incorporated within the controlling unit of the control system. An embodiment ^{incorporating features} ~~for~~ this is shown in Fig. 12. In this embodiment, there are a control system network 20 and an information system network 30. To the control system network 20, an engine controlling unit 40 and an ACC control unit 50 are connected. Also, to the information system network 30, the engine controlling unit 40 and a navigation system 60 are connected. In this embodiment, a gateway function 410 is ^{incorporated} ~~placed~~ within the engine controlling unit 40 ^a ~~to~~ cause the engine controlling unit 40 to have ^a ~~the~~ gateway function. The gateway function 410 can be realized in ^a ~~the~~ similar way to the gateway ^{the previously described} in ^{one} ~~embodiment~~ of this invention. ^{In way} ~~By~~ this, ~~the~~ effect is ^{provided that} there is no need to use an independent gateway, and therefore it is possible to reduce the cost.

In ^{accordance with this} ~~said one~~ embodiment of ^{the} ~~this~~ invention, the function

of the gateway ^{is} [was] realized by means of software, but it is possible to achieve the same function by means of hardware. ^{In way} [By] this, ^{an} [the] effect can be obtained ⁱⁿ that the system is speeded up.

In ^{the above-described} [said one] embodiment of this invention, the control system network for transmitting ^a [the] periodic ~~the~~ message and the information system network for transmitting ^{an} [the] event message were connected, but with a network for transmitting ^a [the] periodic ~~the~~ message and a network for transmitting ^{an} [the] event message, ^{the invention is use of a} [they are] not limited to the control system network and ^{an} [the] information system network, respectively. For example, ^{it is possible to provide} [they may be] a power train system control network using ^a [the] periodic messages and a body system control network using ^a [the] event messages, respectively. Also, ^{the invention is a system having a} [they are] not limited to ^a [the] use in an automobile. For example, ^a [in the] network handling ^a [the] periodic messages and ^a [the] network handling ^a [the] event messages ^{they are} is ^{useful for} ^{applications} [applicable to] many ^{systems} [systems] such as an FA (Factory Automation) system, an electric power system, a railroad system, a steel ^{production} system and the like. ^{In way} [By] this, ^a [there occurs the effect that] in a distributed system having various networks, a high efficiency gateway can be obtained.

[INDUSTRIAL APPLICABILITY]

This invention can be applied to ^{applications} [a field] such as industrial machinery, ^{systems} [an] electric power, ^{production} a railroad, steel, an automobile or the like, in which a plurality of kinds of networks are interconnected.
